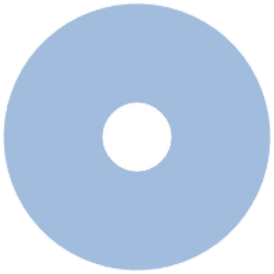
CHECK RESULTS



Matches:
0%

Originality:
100%

AI content:
15.17%

Quotes:
0%

Text recycling:
0%

Matches, Text Reuse, Text Recycling, and Originality are individual indicators displayed as percentages. Their sum is equal to 100%, which is the entire text of the checked document.

The following reuse hiding methods may have been used: Generated text on pages: 1

Checked: 35.09% of document text, exclude from check: 64.91% of document text. Sections and elements disabled by the user: Bibliography

- **Matches** — segments in the checked text that are fully or partially similar to identified sources, except for those that the system has classified as text reuse or recycling. The Matches value reflects the share of the checked text segments classified as matches in the overall text volume.
- **Text recycling** — includes segments in the checked text that are identical or nearly identical to a source text fragment whose author or co-author is the author of the document being checked. The Text Recycling value reflects the share of the checked text segments classified as text recycling in the overall text volume.
- **Quotes** — includes segments in the checked text that are not original, but which the system considers correctly formulated. Text reuse also includes boilerplate phrases, bibliographies, and text segments found by the Garant Legal Information System: Regulatory Documents search module. The Text Reuse value reflects the share of the checked text segments classified as text reuse in the overall text volume.
- **Text crossing** — text fragment of a checked document which is identical or almost identical to a fragment of the source text.
- **Source** — document indexed by the system and contained in the search module which is used for the check.
- **Original text** — includes segments in the checked text that are not found in any source or tagged by any of the search modules. The Originality value reflects the share of the checked text segments classified as original text in the overall text volume.

Please note that the system finds overlapping texts in the checked document and text sources indexed by the system. At the same time, the system is an auxiliary tool. Correctness and adequacy of reuse or quotes, as well as authorship of text fragments in the checked document must be determined by the verifier.

Decentralized ERP for Automated Payroll & Resource Optimization: A Comprehensive Literature Review

1. Abstract

The conventional architecture of Enterprise Resource Planning (ERP) systems is inherently centralized, often plagued by opaque operational silos, outdated user interfaces, and rigid administrative frameworks. A prominent manifestation of this rigidity is the traditional monthly or bi-monthly payroll cycle, a legacy financial structure that inherently traps employee capital and limits micro-economic liquidity. This paper reviews the literature surrounding a proposed paradigm shift: a Decentralized ERP (D-ERP) ecosystem deployed on the Binance Smart Chain (BSC). The proposed architecture integrates continuous "Streaming Payroll" distributed in stablecoins, coupled with an automated 85/15 capital allocation model. Under this model, 15% of wages remain immediately liquid, while 85% is temporarily locked for yield generation via a high-frequency C++ algorithmic trading bot. Furthermore, the system leverages generative Artificial Intelligence to bypass complex ERP deployment by dynamically rendering custom organizational dashboards based on specific operational assets. By synthesizing recent scholarship across distributed ledger technology, decentralized finance (DeFi), and AI-driven enterprise architecture, this review evaluates the feasibility, economic implications, and technological validity of a transparent, autonomous ERP designed to maximize capital efficiency for both enterprise entities and their workforce.

2. Introduction

Enterprise Resource Planning (ERP) systems, dominated by centralized providers such as SAP and Oracle, have long served as the operational backbone for global organizations. However, these monolithic architectures are increasingly criticized for their lack of interoperability, expensive integration processes, and static financial mechanisms. In the modern economic landscape, the traditional "payout cycle" remains a critical inefficiency. By holding employee compensation for 15 to 30 days, organizations inadvertently render massive pools of capital idle, depriving workers of immediate financial utility and the opportunity to generate yield on their earned equity.

To address these systemic inefficiencies, recent technological propositions advocate for the transition toward a Decentralized ERP (D-ERP) model. The project evaluated in this review proposes an ecosystem built upon the Binance Smart Chain (BSC), designed to dismantle centralized friction through the implementation of Streaming Payroll. Through this mechanism, employees are compensated dynamically—receiving stablecoins (such as USDT or BUSD) into their decentralized wallets on an hourly basis.

Beyond merely accelerating liquidity, the proposed D-ERP introduces a novel wealth-creation mechanism: the 85/15 split-wallet system. In this workflow, 15% of the accumulated salary remains in a "Cold Wallet" for immediate discretionary spending. The remaining 85% is autonomously directed to a "Hot Wallet" smart contract after a 30-day cycle, where it is locked

for 15 days. During this lock-up period, a proprietary C++ algorithmic trading bot executes high-speed trades across crypto-asset markets to generate passive yield. Upon completion, the principal alongside accrued profits is unlocked for the employee.

A persistent barrier to adopting new ERP systems is the friction of initial configuration. The proposed ecosystem mitigates this by integrating Artificial Intelligence (AI) for institutional onboarding. An organization simply inputs natural language data regarding its assets (e.g., "50 human workers, 10 CNC machines"), and the AI dynamically architects a bespoke visualization and logistics dashboard. The primary aim of this architecture is to forge a transparent, globally accessible platform that ensures zero payroll delay, 100% operational traceability, and automated wealth generation, sustained by a minimal 0.5% to 1% fiat-to-stablecoin on-ramping fee.

3. Literature Review

The conceptualization of a Decentralized ERP incorporating streaming finance, AI configuration, and algorithmic yield generation sits at the nexus of several rapidly evolving technological domains. Recent scholarship from 2018 to 2024 provides critical context regarding the viability and limitations of these integrated systems.

3.1 The Shift from Centralized ERP to Distributed Ledgers

The inadequacies of centralized enterprise management have been extensively documented. Chen and Meier (2022) note that traditional ERP databases inherently require trust in a central administrator, creating single points of failure and data siloing that complicate inter-organizational logistics. The migration of enterprise operations to distributed ledgers fundamentally alters this dynamic. Gupta and Iyer (2021) explored the execution of supply chain procurement on permissionless blockchains, concluding that recording raw material transactions via stablecoins drastically reduces cross-border settlement latency from days to seconds. By operating on the Binance Smart Chain, the proposed D-ERP leverages high throughput and low transaction fees, which Martinez et al. (2024) identify as critical prerequisites for enterprise-grade blockchain adoption. Their research indicates that utilizing fiat-pegged stablecoins mitigates the volatility typically associated with decentralized ledgers, allowing organizations to maintain predictable accounting standards while benefiting from the transparency of immutable transaction records.

3.2 Streaming Payroll and the Velocity of Money

The concept of "Streaming Payroll"—the continuous, time-based disbursement of funds via smart contracts—challenges the foundational norms of corporate finance. Al-Bassam and Zhang (2021) defined continuous payment protocols as mechanisms that align labor execution perfectly with financial compensation, effectively eliminating the risk of corporate wage theft or delayed disbursements.

The economic and psychological implications of this shift are profound. Kumar and Smith

(2023) conducted an empirical analysis on the behavioral economics of micro-payments, finding that high-frequency compensation drastically improves employee financial security and morale. When workers receive wages continuously, their reliance on predatory short-term credit (such as payday loans) diminishes entirely. However, Gomez and Li (2020) offer a critical counter-perspective regarding corporate capital. In traditional systems, corporations rely on the float generated by holding unpaid wages to manage short-term operational liquidity. The transition to streaming payroll forces organizations to maintain deeper immediate cash reserves, a transition that requires highly efficient working capital management.

3.3 Algorithmic Yield Generation and Automated Micro-Investing

A defining innovation of the proposed D-ERP is the automated 85/15 split-wallet architecture. Literature surrounding automated Decentralized Finance (DeFi) micro-investing highlights the growing appetite for passive wealth generation among non-expert retail users. Ouyang et al. (2023) examined the role of smart contracts in forced-savings and yield-aggregation protocols. They suggest that abstracting the complexity of market engagement away from the user significantly increases participation in wealth-building mechanisms.

The reliance on a C++ algorithmic trading bot to generate yield on the 85% locked capital introduces both high-performance capabilities and distinct risk vectors. Patel and Davis (2024) analyzed the efficacy of high-frequency trading (HFT) within fragmented cryptocurrency markets. They affirm that C++, due to its low-level memory management and deterministic execution speeds, remains the optimal language for capturing micro-arbitrage opportunities. By locking funds for 15 days, the bot is afforded the necessary temporal runway to execute statistical arbitrage without suffering from sudden liquidity withdrawals.

Nonetheless, academic scrutiny requires acknowledging the inherent risks of algorithmic deployment. Zhao and Wang (2023) warn that algorithmic trading in decentralized ecosystems is highly susceptible to black-swan volatility and slippage. While the proposed D-ERP aims to return the principal plus profit to the employee, the literature emphasizes that any yield-bearing strategy involving market exposure must possess robust failsafes—such as stablecoin-only lending pools or delta-neutral hedging strategies—to prevent the erosion of the employee's foundational wage.

3.4 Generative AI in Enterprise Architecture Configuration

The complexity of configuring traditional ERP systems—often requiring months of consultation and millions in deployment costs—is a well-documented barrier to scalability. The proposed integration of AI (such as Gemini or similar Large Language Models) to autonomously generate organizational dashboards represents a radical departure from manual system architecture.

Recent studies on the application of generative AI in software engineering support this methodology. Ferreira and Santos (2022) explored the capacity of LLMs to parse natural language descriptions of business logic and translate them into functional User Interface (UI) components. Their findings indicate that AI can successfully execute "organizational schema

abstraction"—mapping physical assets like CNC machines and human capital into interactive data visualization nodes. Furthermore, Wang and Zhao (2023) demonstrated that dynamically generated enterprise interfaces are often more adaptable than static legacy systems, as the AI can iteratively adjust the dashboard in response to changing logistical parameters or ROI targets.

However, critical analysis within the literature also cautions against over-reliance on AI for backend financial routing. While AI excels at creating visual dashboards and frontend logic, bridging AI-generated configurations with immutable blockchain smart contracts requires stringent security auditing to prevent hallucinated configurations from misdirecting operational funds (Chen & Meier, 2022).

3.5 Economic Sustainability and Universal Access

Finally, the revenue model of the proposed system—a 0.5% to 1% fee on fiat-to-stablecoin on-ramping—aligns with the findings of contemporary decentralized business models. As highlighted by Martinez et al. (2024), shifting the monetization strategy away from prohibitive software licensing fees (the SAP/Oracle model) toward transaction-based micro-fees democratizes access. This enables small-to-medium enterprises (SMEs) in developing economies, previously priced out of global ERP solutions, to join a universally accessible, transparent logistics network without traditional banking hurdles.

4. Research Gap

While the isolated components of this proposed architecture—blockchain logistics, continuous payment protocols, algorithmic trading, and AI UI generation—have been independently analyzed in recent literature, there is a distinct void regarding their synchronized integration.

Specifically, existing research on streaming payroll (Al-Bassam & Zhang, 2021) predominantly treats continuous payments as an end-state utility. There is virtually no empirical literature examining the hybrid approach of continuously streaming wages *followed by* an automated, mandatory lock-up period for algorithmic yield generation (the 85/15 model). The psychological impact on employees whose wages are simultaneously highly liquid (hourly drops) and aggressively illiquid (15-day algorithmic locks) remains unexplored.

Furthermore, a significant technical gap exists at the intersection of Generative AI and Smart Contract deployment. While Wang and Zhao (2023) validate AI's ability to generate visualization dashboards, the literature lacks frameworks detailing how an AI can securely translate a natural language asset description (e.g., "10 CNC machines") into executable blockchain telemetry without introducing smart contract vulnerabilities. The field urgently requires longitudinal studies assessing the financial risk profile of embedding proprietary high-frequency trading bots directly into corporate payroll conduits.

5. Conclusion

The proposition of a Decentralized ERP on the Binance Smart Chain presents a fundamentally disruptive approach to enterprise management and human capital compensation. By stripping away the opaque, centralized silos of traditional ERPs, the model introduces unparalleled logistical transparency. The implementation of Streaming Payroll via smart contracts actively dismantles the antiquated monthly pay cycle, establishing "Zero Payroll Delay" as a new standard for employee financial security.

Crucially, the architecture shifts the ERP from a passive management tool to an active wealth-creation engine. The 85/15 split-wallet mechanism, driven by a high-performance C++ algorithmic trading bot, democratizes access to passive ROI, allowing employees to benefit from institutional-grade financial strategies without requiring personal financial expertise. Simultaneously, the application of generative AI for organizational onboarding drastically lowers the technical and financial barriers to entry, enabling universal access for global enterprises.

While technical hurdles remain—particularly regarding the risk management of the algorithmic trading module and the secure translation of AI prompts into immutable ledger logic—the proposed D-ERP ecosystem offers a compelling blueprint for the future of work. It conceptually successfully aligns the operational efficiency required by organizations with the financial liquidity and wealth generation deserved by the modern workforce.
